# Overview

## Overview

- **Introduction and Historical Background**
- **Interfere-o-what?**
- **Science Motivations and Potential Missions**

## Objectives and Outcomes

- **Heuristic understanding of interferometry**  
a.k.a. possible to construct large synthetic telescopes by combining small ones in appropriate manner
- **Appreciation for science motivations and rationale for potential future space missions**
- **Understanding that astronomy is conducted at many different wavelengths (colors of light) and that different wavelengths provide different information about the Universe**

# Aside

Joseph Lazio

## Who?

- **Chief Scientist, NASA's Deep Space Network**
- **Boy who always wanted to grow up to be radio astronomer**
- **Involved in early development of Low Frequency Array (LOFAR) and Long Wavelength Array (LWA)**
- **Former Project Scientist for Square Kilometre Array (SKA)**
- **Involved in multiple lunar radio telescope concepts**
- **Project Scientist for space-based interferometer under consideration by NASA**

# Historical Background

Pre-20<sup>th</sup> Century

**Human eye capable of diffraction-limited imaging of about 1 arcminute**

**20/20 vision ~ U.S. quarter across football pitch**

Credit: Micael W. Davidson,  
(Florida State Univ.)

**Modest optical  
telescopes provide  
diffraction-limited  
imaging at 1  
arcsecond  
resolution  
60× better**

# Angular Resolution and Optics

Can Two Stars Be Split?

## Fundamental optics

$$\theta = \lambda/D$$

- $\lambda$  = observing wavelength
- $D$  = diameter of aperture

Credit:  
Spencer Bliven

# Angular Resolution and Optics

## Human Eye

- $\lambda \sim 550 \text{ nm}$  ( $\sim 0.00055 \text{ mm}$ )
  - observing wavelength
  - green-yellow light
- $D \sim 5 \text{ mm}$ 
  - diameter of pupil (aperture)
- ✓  $\theta \sim 0.00011 \text{ radians} \sim 0.0063^\circ \sim 0.4 \text{ arcminutes}$   
 $\theta = \lambda/D$

# Electromagnetic Spectrum

# Full View of the Universe

**MS 0735.6+7421**

- **Cluster of galaxies**
  - About 2.6 billion light-years away
  - In the constellation Camelopardalis
- **Three views**
  - **Blue:** Chandra X-ray Observatory
  - **White:** *Hubble Space Telescope*
  - **Red:** Very Large Array

Hubble and Chandra: NASA, ESA, CXC, STScI, B. McNamara (Univ. of Waterloo)  
Very Large Array: NRAO, L. Birzan and team (Ohio Univ.)

# Interferometry

# Angular Resolution and Optics

## Radio Telescopes

- $\lambda \sim 0.30 \text{ m}$  ( $\sim 1 \text{ GHz}$ )
- $D \sim 300 \text{ m}$   
diameter of telescope
- $\theta = 0.001 \text{ radians} \sim 0.06^\circ \sim 3 \text{ arcminutes}$   
 $\theta = \lambda/D$
- ! Your eye has higher angular resolution than Arecibo telescope!

# Angular Resolution and Optics

## Radio Telescopes

- Arecibo diameter  $\sim 300$  m
- ?? Match angular resolution of human eye  $\sim 1$  km
- ?? Match angular resolution of modest visible wavelength telescope  $\sim 10$  km

# Angular Resolution and Optics

## Radio Telescopes

**Arecibo has hole in its middle!**

**How many holes can a telescope have and still work?**

# How Do Telescopes Work?

## Exercise for the reader:

Consider a parabolic surface.

Show that initially parallel light rays, all traveling at the speed of light  $c$ , reach a common point, *the focus*, at the same time no matter where they reflect from the surface of the reflector.

**Extra credit:** Repeat for a spherical reflector such as Arecibo and show that the focus is a line.

# Aperture Synthesis

1. Record signals at individual antennas
2. Bring them together “at the same time” (coherently)
3. Then ...

# Interferometry or Aperture Synthesis

1. Record signals at individual antennas
2. Bring them together “at the same time” (coherently),
3. Then synthesize aperture!  
a.k.a. build a telescope that’s mostly holes!

# Aperture Synthesis

Extra path length:  
 $x = b \sin \psi$

Geometric delay:  
 $\tau_g = x/c = (b/c) \sin \psi$

# Aperture Synthesis

Extra path length:  
 $x = b \sin \psi$

Geometric delay:  
 $\tau_g = x/c = (b/c) \sin \psi$

$\tau$

# Conceptual Radio Telescope

**\*Today: Record to hard drive disk packs or even direct streaming across the Internet**  
**Historical note: Record on magnetic tapes, including VHS tapes**

# Aperture Synthesis

Geometric delay:  
 $\tau_g = x/c = (b/c) \sin \psi$

Need to know  
where antennas are

- *Knowledge*, not control
- Only *relative* positions

# Earth Rotation Synthesis

**Geometric delay:**  
 $\tau_g = x/c = (b/c) \sin \psi$

➤ From perspective of distant observer, array changes shape

# Aperture Synthesis Fundamentals

# Aperture Synthesis Fundamentals

$$\tau_g = (b/c) \sin \psi$$

$$\text{Output} = \sin(2\pi\nu t) \sin[2\pi\nu(t - \tau_g)]$$

$$\text{Output} = \sin^2(2\pi\nu t) \cos(2\pi\nu\tau_g) - \sin(2\pi\nu t) \cos(2\pi\nu t) \sin(2\pi\nu\tau_g)$$

Average for  $T \gg 1/\nu$  or take  $\nu T \gg 1$

$$\sin^2(\text{big number}) \rightarrow 1/2$$

$$\sin(\text{big number}) = \cos(\text{big number}) = 0$$

➤  $\text{Output} = \cos(2\pi\nu\tau_g)$

➤  $\text{Output} = \cos(2\pi[b/\lambda]\sin \psi)$

# Aperture Synthesis Fundamentals

$$\tau_g = (b/c) \sin \psi$$

$$\text{Output} = \sin(2\pi\nu t) \sin[2\pi\nu(t - \tau_g)]$$

$$\text{➤ Output} = \cos(2\pi[b/\lambda] \sin \psi)$$

Thompson,  
Moran, &  
Swenson

# Aperture Synthesis Fundamentals

# Aperture Synthesis Fundamentals

# Aperture Synthesis Fundamentals

$$\theta = \lambda/D$$

$$\theta \rightarrow \ell$$

$$D = b$$

$$u = D/\lambda$$

➤ **Output =  $\sum_{\ell} \cos(2\pi u \ell)$**

**$u = b/\lambda$  and  $\ell$  are Fourier conjugates**

➤ **Big  $u$  means small  $\ell$ ; small  $u$  means big  $\ell$**

# Aperture Synthesis Fundamentals

## Mid-Term Review

- ✓ **Receptor/antenna separation, measured in wavelengths, is equivalent to aperture diameter.**  
True for any optical instrument, not just synthetic apertures
- ✓ **Baselines (a.k.a. antenna separations) determines angular resolution.**  
Distribution of baselines affects performance of synthetic aperture a.k.a. no free lunch theorem.
- ✓ **Knowledge of relative antenna separations is critical.**

# Aperture Synthesis

1974 Nobel Prize in Physics

The Nobel Prize in Physics 1974 was awarded jointly to Sir Martin Ryle and Antony Hewish "for their pioneering research in radio astrophysics: **Ryle** for his observations and inventions, in particular of the **aperture synthesis technique**, and *Hewish for his decisive role in the discovery of pulsars.*"

# Aperture Synthesis Fundamentals

$$\theta = \lambda/D$$

✓ Big  $u$  (or large  $b$ ) means small  $\ell$

• Small  $u$  (or small  $b$ ) means big  $\ell$

“largest angular scale”

**Whoa!**

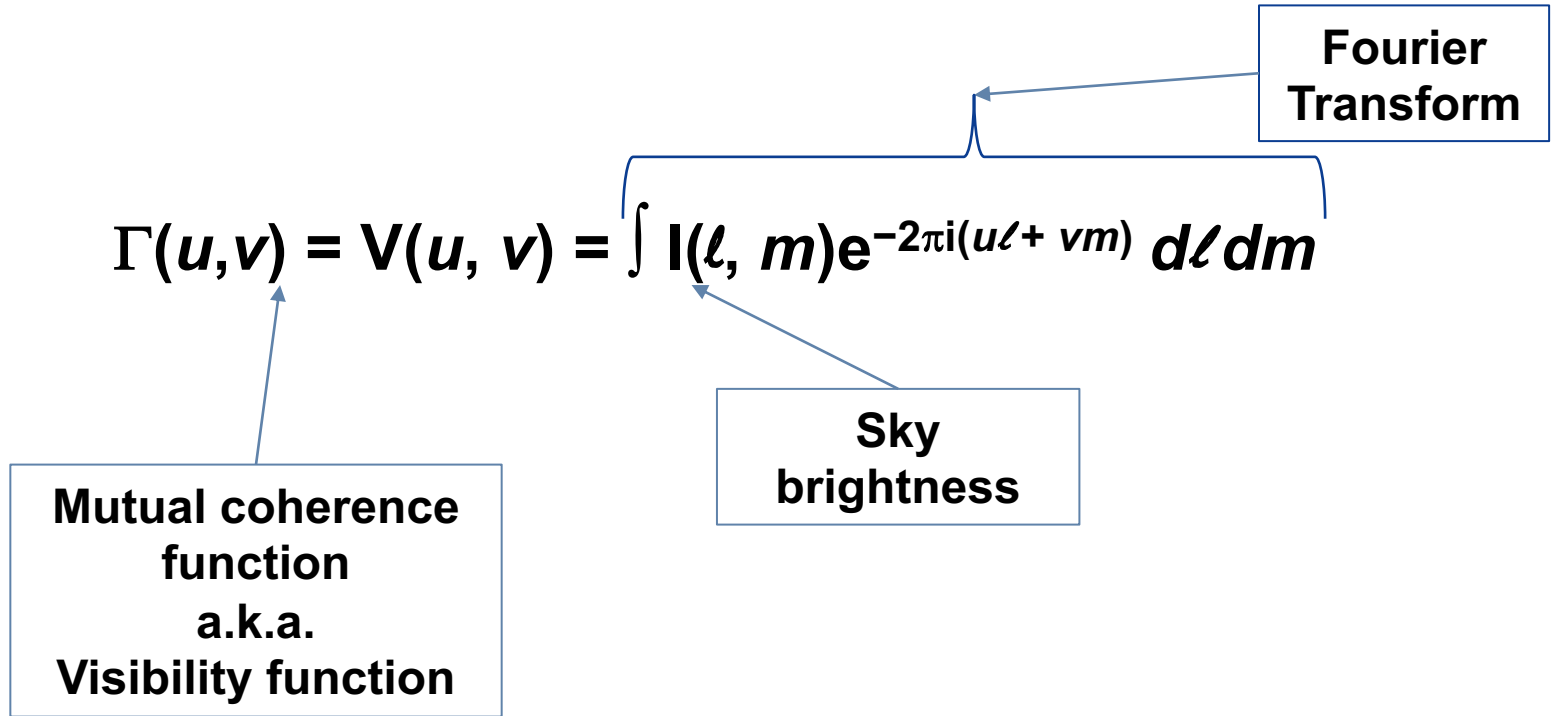

# Van Cittert-Zernike Theorem

Heuristic:     Output =  $\sum_{\ell} \cos(2\pi u\ell)$

$$\Gamma(u, v) = V(u, v) = \int I(\ell, m) e^{-2\pi i (u\ell + vm)} d\ell dm$$

# Van Cittert-Zernike Theorem

# Van Cittert-Zernike Theorem

$$\Gamma(u, v) = V(u, v) = \int I(\ell, m) e^{-2\pi i (u\ell + vm)} d\ell dm$$

## Assumptions

- **Narrow field of view**
- **Co-planar array**
- **Monochromatic signals (narrow bandwidths)**
- **Instantaneous signal reception**

# Aperture Synthesis

$$\Gamma_{12}(u, v)$$

$$\Gamma_{13}(u, v)$$

$$\Gamma_{14}(u, v)$$

.

.

.

$$\Gamma_{ij}(u, v)$$

$$I(\ell, m) = \text{FT}[\Gamma(u, v)]$$

# Visibilities, $u$ - $v$ Plane, (Synthesized) Beams

$$u = 40,000$$

$$b_x = 40,000\lambda$$

$$\lambda \sim 6 \text{ cm } (\sim 5 \text{ GHz})$$

$$b_x \sim 2.4 \text{ km}$$

Aperture is 2.4 km in size!

Resolution  $\sim 5''$

Remember where we  
started?!

# Visibilities, $u$ - $v$ Plane, (Synthesized) Beams

$$I(\ell, m) = \text{FT}[\Gamma(u, v)]$$

Sky brightness  $I(\ell, m)$  is real quantity

$$\Gamma(u, v) = \Gamma^*(u, v) = \Gamma(-u, -v)$$

# Visibilities, $u$ - $v$ Plane, (Synthesized) Beams

$$u = b_x/\lambda$$

Sample range of  $\lambda$  or  $\nu$ , get range of  $(u, v)$

➤ Fill in synthetic aperture

# Visibilities, $u$ - $v$ Plane, (Synthesized) Beams

$$u = b_x/\lambda$$

Baselines change as Earth rotates,  $b = b(t)$

Sample over range of time, get range of  $(u, v)$

➤ Fill in synthetic aperture

# Visibilities, $u$ - $v$ Plane, (Synthesized) Beams

$\Pi(u, v) = 1$  if measured

$\Pi(u, v) = 0$  if not measured

Beam = FT[ $\Pi(u, v)$ ]

a.k.a. point spread function

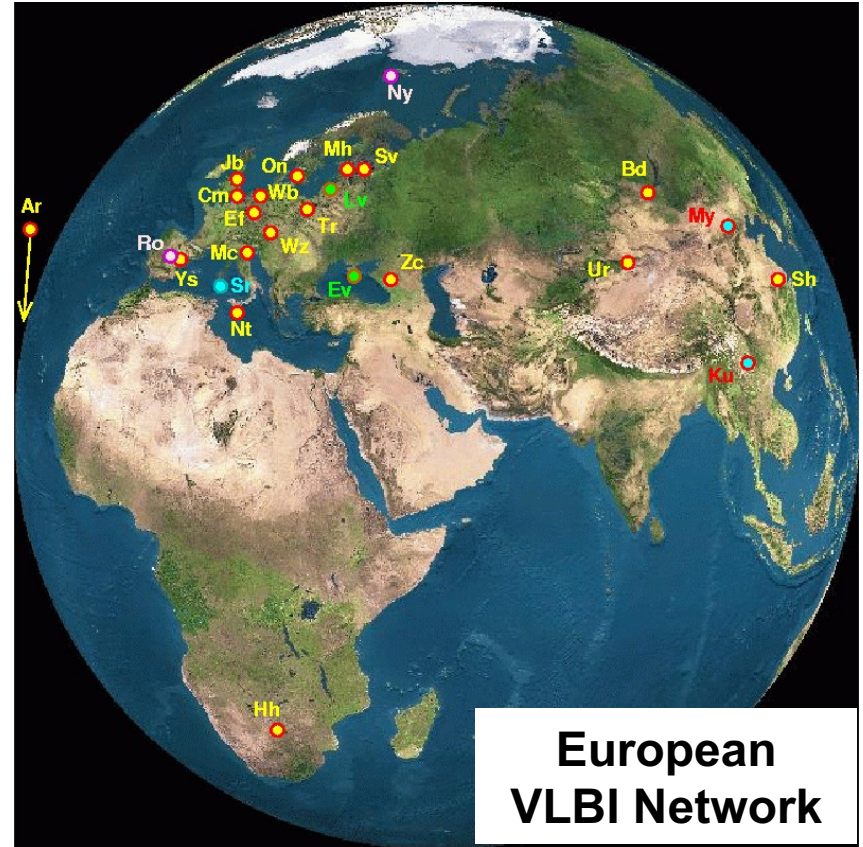

**Sidelobes!**

Measure of performance  
of telescope

# Very Long Baseline Interferometry

**Very Long  
Baseline Array**

**European  
VLBI Network**

# Space-based Interferometry

# How Small Can Radio Sources Be?

## Space-based Interferometry

- By mid-1970s, clear that some radio sources still unresolved on terrestrial baselines
- Also superluminal motion apparent
- Heuristically, if source too small, energy density not enough to be visible to terrestrial radio interferometers?
  - A.k.a. no free lunch theorem  
As synthetic apertures, interferometers limited to observing bright sources, because telescope with lots of holes
  - Inverse Compton catastrophe

# VLBI Space Observatory Program (VSOP) / HALCA

**JAXA-led  
8 m-diameter space-  
based antenna**

- **Some sources still have point-like or unresolved components, implies physics about central engines**

**Coherent or Doppler-beamed emitters**

# RadioAstron

**Roscosmos-led  
10 m-diameter  
space-based  
antenna**

**Baselines  
comparable to  
Earth-Moon  
distance**

# Black Hole Event Horizon Imaging

## Space-based Interferometry

- In Einstein's General Relativity, black hole is volume disconnected from rest of Universe
- **Event horizon** is boundary between inside black hole and rest of Universe

Schwarzschild radius

For Sun,  $R_s \cong 3 \text{ km}$

$$R_g = R_s \equiv \frac{2GM}{c^2}$$

# Black Hole Event Horizon Imaging

Credit: Moondigger

Space Interferometry

[jpl.nasa.gov](https://jpl.nasa.gov)

# Black Hole Event Horizon Imaging

## Space-based Interferometry

$$M \sim 4 \times 10^6 M_{\odot}$$

$$2R_g/D_{GC} = \sin \ell \sim \ell$$

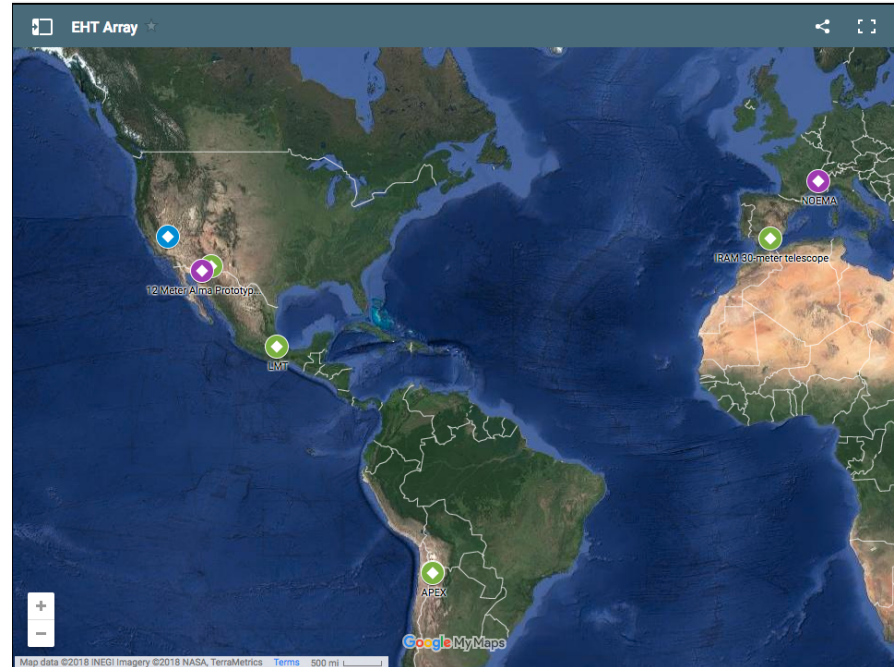

- $R_g \sim 12 \times 10^6 \text{ km}$
- $D_{GC} \sim 8000 \text{ pc } (\sim 2.5 \times 10^{17} \text{ km} \sim 26,000 \text{ light years})$
- $\ell \sim 9.7 \times 10^{-11} \text{ radians} \sim 20 \text{ microarcseconds}$

# Black Hole Event Horizon Imaging

## Space-based Interferometry

**Need ~ 10 microarcsecond resolution**

- **Choose  $\lambda \sim 0.13$  cm**
- **$b \sim 10,000$  km**
- **Event Horizon Telescope = Earth-scale telescope to image nearby black hole event horizons**
  - **See April 10 press release**

# Black Hole Event Horizon Imaging

## M87 in Virgo

# Black Hole Event Horizon Imaging

Space-based Interferometry

**Nominal Event Horizon  
Telescope is extremely  
sparse array**

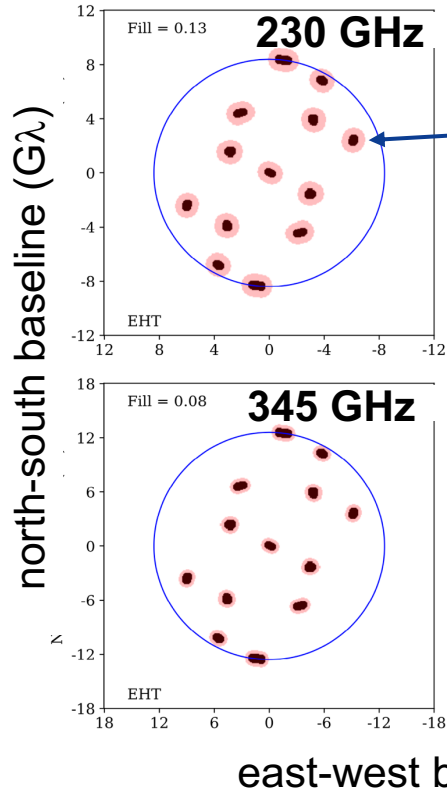

# Black Hole Event Horizon Imaging

## EHT is sparse array

- Many "holes" in synthetic aperture
    - ... or many holes in  $u$ - $v$  plane or Fourier plane
  - Earth-rotation synthesis
    - 1 rotation = 24 hr
- Any way to fill these  $u$ - $v$  plane holes?

# Black Hole Event Horizon Imaging

ground-ground baselines

space-ground baselines

- **Spacecraft in low-Earth orbit (LEO) has 90 minute orbital period**
- **Antenna on LEO spacecraft would fill  $u-v$  plane dramatically!**

# Electromagnetic Spectrum

# Solar Radio Bursts

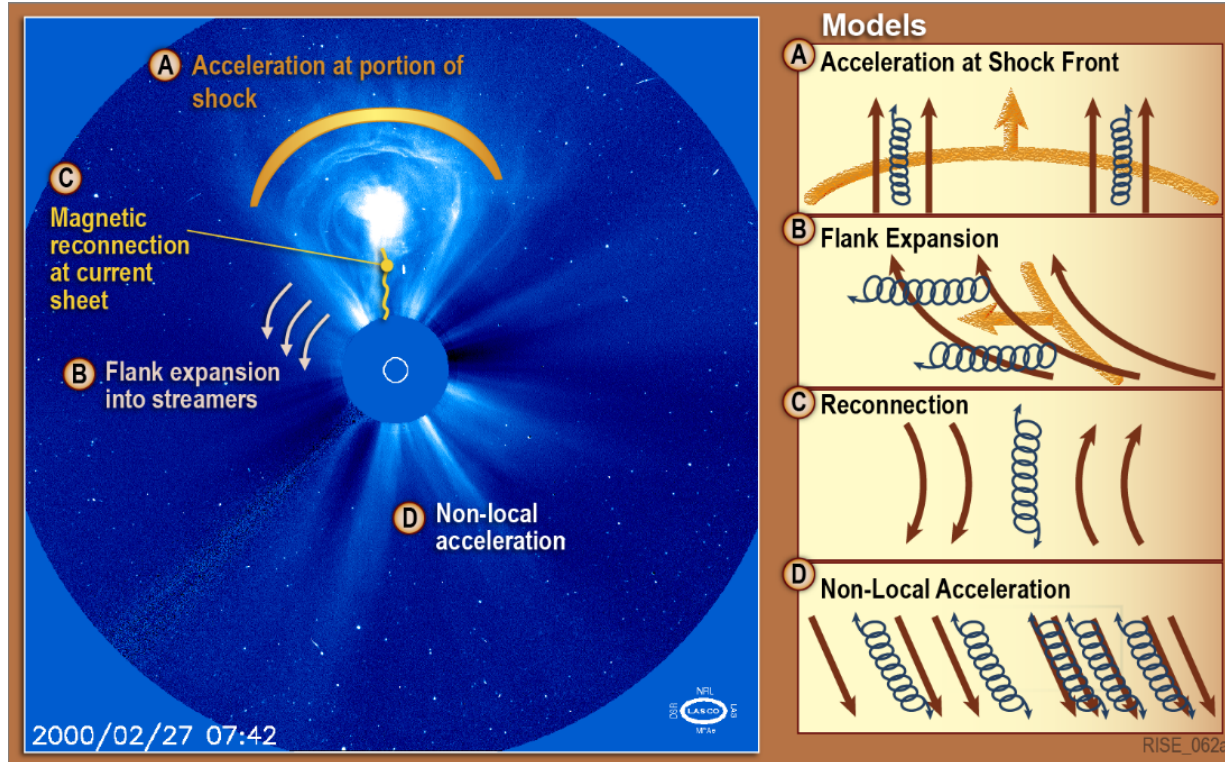

Type II and III

Slowly descending in frequency as coronal mass ejections expand into heliosphere

# Classes of Models for Ion and Electron Acceleration by CMEs

- (A) Shock and compression acceleration in front of CME as it expands into corona**
- (B) Shock and compression acceleration on flanks as CME expands laterally into quiet streamers**
- (C) Magnetic reconnection at current sheets behind the ejecta**
- (D) Non-local acceleration as plasma is diverted and compressed by expanding filament**

# SunRISE

- First full interferometer in space, first decametric-hectometric (DH) imaging
  - Loose formation of six 6U form factor smallsats in approximate 10 km sphere
  - GEO Plus Orbit (25 hr orbit period)
  - Radio receiver (0.1 MHz – 20 MHz) with crossed 5 m dipole antennas
  - Relative position knowledge to within 3 m, timing to nanoseconds
- Need access to space because Earth's ionosphere is opaque!
- If selected, notional launch in 2023

# SunRISE Spacecraft and Science Instrument

# SunRISE Orbitology and $u$ - $v$ plane

# Beyond the Radio

# Summary

- **High angular resolution imaging demands large apertures**
- **Interferometry is powerful (only) way to synthesize large apertures**  
Depends on relative antenna separations, knowledge not control
- **Exciting future space possibilities for opening new windows, peering at black holes in new ways**

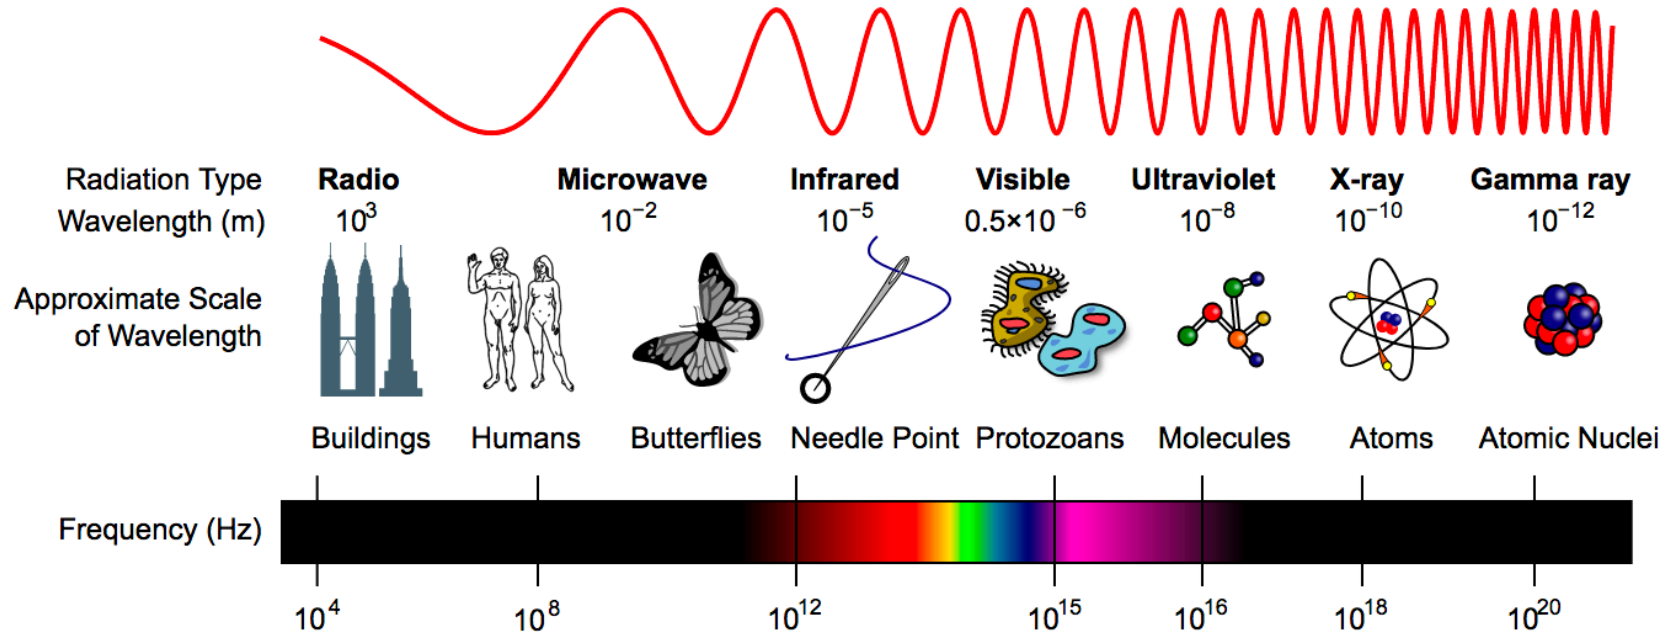

**Jet Propulsion Laboratory**
